Main topics of the week:
- Review problems for midterm

**Problem**: Let $\Sigma = \{0,1\}$ and $A = \{ w \in \Sigma^* | \text{w does not contain a pair of 1's separated by an odd number of symbols} \}$. Show that $A$ is a regular language.

*Proof:*

**Problem**: Let $A$ be a regular language over the alphabet $\Sigma$. Show that $B = \{ x | x = yz \text{ for some } y \in A \text{ and some string } z \in \Sigma^* \}$ is a regular language.

*Proof:*

**Problem**: Let $A$ be the language $\{a^ib^ja^k | k > i + j \}$. Prove that $A$ is not regular.

*Proof:*

**Problem**: Let $A$ be the language $\{(ab)^n a^k | n > k \text{ and } k \geq 0 \}$. Prove that $A$ is not regular.

*Proof:*

**Problem**: Prove that the reverse of a regular language is a regular language.

*Proof:*

**Problem**: An All-Paths-NFA is a 5-tuple $(Q, \Sigma, \delta, q_0, F)$ like an NFA except that this automaton accepts a string if *every possible computation* of the string ends in an accept state. (Recall that in a regular NFA, if *some* computation ends in an accept state, then the string is accepted.) Prove that a language is regular if and only if it is recognized by an All-Paths-NFA.

*Proof:*
