Introduction to Artificial Intelligence

Lecture 16: Bayes Nets - Sampling

Thanh H. Nguyen

Source: http://ai.berkeley.edu/home.html
Bayes' Nets

- Representation
- Conditional Independences
  - Probabilistic Inference
    - Enumeration (exact, exponential complexity)
    - Variable elimination (exact, worst-case exponential complexity, often better)
    - Inference is NP-complete
      - Sampling (approximate)
  - Learning Bayes’ Nets from Data
Approximate Inference: Sampling
Sampling is a lot like repeated simulation

Predicting the weather, basketball games, ...

Basic idea

Draw N samples from a sampling distribution S

Compute an approximate posterior probability

Show this converges to the true probability P

Why sample?

Learning: get samples from a distribution you don’t know

Inference: getting a sample is faster than computing the right answer (e.g. with variable elimination)
Sampling

Sampling from given distribution

- Step 1: Get sample $u$ from uniform distribution over $[0, 1)$
  - E.g. random() in python
- Step 2: Convert this sample $u$ into an outcome for the given distribution
  - Each target outcome is associated with a sub-interval of $[0, 1)$
  - Sub-interval size is equal to probability of the outcome.

Example

<table>
<thead>
<tr>
<th>C</th>
<th>P(C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td>0.6</td>
</tr>
<tr>
<td>green</td>
<td>0.1</td>
</tr>
<tr>
<td>blue</td>
<td>0.3</td>
</tr>
</tbody>
</table>

- If random() returns $u = 0.83$, then our sample is $C = \text{blue}$
- E.g, after sampling 8 times:
Sampling in Bayes' Nets

</table>

Samples:
+ c, -s, +r, +w
- c, +s, -r, +w
...

Cloudy

Sprinkler

Rain

WetGrass
Prior Sampling

- For $i = 1, 2, \ldots, n$
  - Sample $x_i$ from $P(X_i \mid \text{Parents}(X_i))$
- Return $(x_1, x_2, \ldots, x_n)$
Prior Sampling

- This process generates samples with probability:

\[ S_{PS}(x_1 \ldots x_n) = \prod_{i=1}^{n} P(x_i|\text{Parents}(X_i)) = P(x_1 \ldots x_n) \]

...i.e. the BN’s joint probability

- Let the number of samples of an event \( N_{PS}(x_1 \ldots x_n) \)

- Then

\[
\lim_{N \to \infty} \hat{P}(x_1, \ldots, x_n) = \lim_{N \to \infty} N_{PS}(x_1, \ldots, x_n)/N
= S_{PS}(x_1, \ldots, x_n)
= P(x_1 \ldots x_n)
\]

- I.e., the sampling procedure is consistent
Example

- We’ll get a bunch of samples from the BN:
  - +c, -s, +r, +w
  - +c, +s, +r, +w
  - -c, +s, +r, -w
  - +c, -s, +r, +w
  - -c, -s, -r, +w

- If we want to know P(W)
  - We have counts <+w:4, -w:1>
  - Normalize to get P(W) = <+w:0.8, -w:0.2>
  - This will get closer to the true distribution with more samples
  - Can estimate anything else, too
  - What about P(C | +w)? P(C | +r, +w)? P(C | -r, -w)?
  - Fast: can use fewer samples if less time (what’s the drawback?)
Rejection Sampling
Rejection Sampling

- Let’s say we want $P(C)$
  - No point keeping all samples around
  - Just tally counts of $C$ as we go

- Let’s say we want $P(C \mid +s)$
  - Same thing: tally $C$ outcomes, but ignore (reject) samples which don’t have $S=+s$
  - This is called rejection sampling
  - It is also consistent for conditional probabilities (i.e., correct in the limit)
Rejection Sampling

- Input: evidence instantiation
- For $i = 1, 2, \ldots, n$
  - Sample $x_i$ from $P(X_i \mid \text{Parents}(X_i))$
  - If $x_i$ not consistent with evidence
    - Reject: return – no sample is generated in this cycle
- Return $(x_1, x_2, \ldots, x_n)$
Likelihood Weighting
Likelihood Weighting

- Problem with rejection sampling:
  - If evidence is unlikely, rejects lots of samples
  - Evidence not exploited as you sample
  - Consider $P(\text{Shape} | \text{blue})$

- Idea: fix evidence variables and sample the rest
  - Problem: sample distribution not consistent!
  - Solution: weight by probability of evidence given parents

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Weighting</th>
</tr>
</thead>
<tbody>
<tr>
<td>pyramid, green</td>
<td>pyramid, blue</td>
</tr>
<tr>
<td>pyramid, red</td>
<td>pyramid, blue</td>
</tr>
<tr>
<td>sphere, blue</td>
<td>sphere, blue</td>
</tr>
<tr>
<td>cube, red</td>
<td>cube, blue</td>
</tr>
<tr>
<td>sphere, green</td>
<td>sphere, blue</td>
</tr>
</tbody>
</table>

Shapes: pyramid, sphere, cube
Colors: blue, green
Likelihood Weighting

\[ P(C) \]

\[
\begin{array}{c|c}
+c & 0.5 \\
-c & 0.5 \\
\end{array}
\]

\[ P(S|C) \]

\[
\begin{array}{c|c|c}
+c & +s & 0.1 \\
-s & 0.9 \\
-c & +s & 0.5 \\
-s & 0.5 \\
\end{array}
\]

\[ P(R|C) \]

\[
\begin{array}{c|c|c}
+c & +r & 0.8 \\
-r & 0.2 \\
-c & +r & 0.2 \\
-r & 0.8 \\
\end{array}
\]

\[ P(W|S, R) \]

\[
\begin{array}{c|c|c|c|c}
+s & +r & +w & 0.99 \\
 & -w & 0.01 \\
-r & +w & 0.90 \\
 & -w & 0.10 \\
-s & +r & +w & 0.90 \\
 & -w & 0.10 \\
 & +w & 0.01 \\
 & -w & 0.99 \\
\end{array}
\]

Samples:

+\(c\), +\(s\), +\(r\), +\(w\)

\[ w = 1.0 \times 0.1 \times 0.99 \]
Likelihood Weighting

- Input: evidence instantiation
- $w = 1.0$
- for $i = 1, 2, \ldots, n$
  - if $X_i$ is an evidence variable
    - $X_i = \text{observation } x_i \text{ for } X_i$
    - Set $w = w \times P(x_i | \text{Parents}(X_i))$
  - else
    - Sample $x_i$ from $P(X_i | \text{Parents}(X_i))$
- return $(x_1, x_2, \ldots, x_n), w$
Likelihood Weighting

- Sampling distribution if \( z \) sampled and \( e \) fixed evidence

\[
S_{WS}(z, e) = \prod_{i=1}^{l} P(z_i|\text{Parents}(Z_i))
\]

- Now, samples have weights

\[
w(z, e) = \prod_{i=1}^{m} P(e_i|\text{Parents}(E_i))
\]

- Together, weighted sampling distribution is consistent

\[
S_{WS}(z, e) \cdot w(z, e) = \prod_{i=1}^{l} P(z_i|\text{Parents}(z_i)) \prod_{i=1}^{m} P(e_i|\text{Parents}(e_i))
\]

\[
= P(z, e)
\]
Likelihood Weighting

- Likelihood weighting is good
  - We have taken evidence into account as we generate the sample
  - E.g. here, W’s value will get picked based on the evidence values of S, R
  - More of our samples will reflect the state of the world suggested by the evidence

- Likelihood weighting doesn’t solve all our problems
  - Evidence influences the choice of downstream variables, but not upstream ones (C isn’t more likely to get a value matching the evidence)
  - We would like to consider evidence when we sample every variable (leads to Gibbs sampling)
Gibbs Sampling
Gibbs Sampling

- **Procedure:** keep track of a full instantiation $x_1, x_2, ..., x_n$. Start with an arbitrary instantiation consistent with the evidence. Sample one variable at a time, conditioned on all the rest, but keep evidence fixed. Keep repeating this for a long time.

- **Property:** in the limit of repeating this infinitely many times the resulting samples come from the correct distribution (i.e. conditioned on evidence).

- **Rationale:** both upstream and downstream variables condition on evidence.

- In contrast: likelihood weighting only conditions on upstream evidence, and hence weights obtained in likelihood weighting can sometimes be very small. Sum of weights over all samples is indicative of how many “effective” samples were obtained, so we want high weight.
Gibbs Sampling Example: \( P( S | +r) \)

- **Step 1: Fix evidence**
  - \( R = +r \)

- **Step 2: Initialize other variables**
  - Randomly

- **Steps 3: Repeat**
  - Choose a non-evidence variable \( X \)
  - Resample \( X \) from \( P( X | \text{all other variables}) \)

Sample from \( P(S | +c, -w, +r) \)  
Sample from \( P(C | +s, -w, +r) \)  
Sample from \( P(W | +s, +c, +r) \)
Efficient Resampling of One Variable

- Sample from \( P(S \mid +c, +r, -w) \)

\[
P(S\mid +c, +r, -w) = \frac{P(S, +c, +r, -w)}{P(+c, +r, -w)} = \frac{P(S, +c, +r, -w)}{\sum_s P(s, +c, +r, -w)}
\]

\[
= \frac{P(+c)P(S\mid +c)P(+r\mid +c)P(-w\mid S, +r)}{\sum_s P(+c)P(s\mid +c)P(+r\mid +c)P(-w\mid s, +r)}
\]

\[
= \frac{P(+c)P(S\mid +c)P(+r\mid +c)P(-w\mid S, +r)}{P(+c)P(+r\mid +c)\sum_s P(s\mid +c)P(-w\mid s, +r)}
\]

\[
= \frac{P(S\mid +c)P(-w\mid S, +r)}{\sum_s P(s\mid +c)P(-w\mid s, +r)}
\]

- Many things cancel out – only CPTs with S remain!

- More generally: only CPTs that have resampled variable need to be considered, and joined together
Bayes' Net Sampling Summary

- Prior Sampling $P(Q)$
- Likelihood Weighting $P(Q | e)$
- Rejection Sampling $P(Q | e)$
- Gibbs Sampling $P(Q | e)$
Further Reading on Gibbs Sampling*

- Gibbs sampling produces sample from the query distribution \( P( Q | e ) \) in limit of re-sampling infinitely often.

- Gibbs sampling is a special case of more general methods called Markov chain Monte Carlo (MCMC) methods.
  - Metropolis-Hastings is one of the more famous MCMC methods (in fact, Gibbs sampling is a special case of Metropolis-Hastings).

- You may read about Monte Carlo methods – they’re just sampling.
